List of Acceptable Hybrids for 1976	25

Performance of Corn Hybrids in Alabama, 1975

David H. Teem^{1/}

Corn performance tests were conducted at 13 locations by the Auburn University Agricultural Experiment Station in 1975. These tests are conducted annually to determine relative production of many hybrids offered for sale and to furnish unbiased information by which growers may choose hybrids. They are designed to permit a comparison of hybrids entered in each test and are not intended for use as an absolute measure of the yielding potential of a hybrid in an area. Careful consideration should be given to all performance characteristics when choosing a hybrid since the proper choice may mean the difference between profit and loss.

Rainfall distribution was good during the 1975 growing season and high yields were obtained in most tests. Yields of more than 100 bushels per acre were obtained at 11 of the 13 locations. Lodging data was not recorded at Auburn, Tallassee, Prattville, and Camp Hill due to wind damage from hurricane Eloise on September 23, 1975.

Location of the tests and cultural practices used are shown in Table 1. Lime and fertilizer were applied in adequate amounts. For weed control either chemical, mechanical, or a combination were used as needed. The experimental design was a split-block with four replications. Yields were adjusted to 15.5 percent moisture and calculated at 56 pounds per bushel. Stalks broken below the ear or leaning more than 45 degrees were considered lodged. Ear rot, earworm damage, size of ear and grain, and luster of grain were considered in rating ear and grain quality. Height of ears was measured from ear base to the ground

^{1/} Research Associate, Department of Agronomy and Soils

level. Husks were rated by tightness and extension beyond the tip of the ear.

Regional averages for 3, 2, and 1 years in northern Alabama are presented in tables 2, 3, and 4, respectively. Table 5 shows yields by location and regional average yields for 1-5 years in northern Alabama. Similar data are shown for central Alabama in tables 6-9 and for southern Alabama in tables 10-13. The performance of corn hybrids planted in 30-inch rows and irrigated at Camden for 1 and 2 years is shown in tables 14 and 15 respectively. In 1975 this test was furrow irrigated on June 26, July 14, and July 20 with 1.5, 2.0, and 2.0 inches of water respectively. The performance of corn hybrids at the Black Belt Substation for 1 and 2 years is shown in tables 16 and 17 respectively. Maize chlorotic dwarf virus (MCDV) and maize dwarf mosaic virus (MDMV) ratings were made on hybrids in the 1975 test at the Black Belt Substation and are shown in table 16. Ratings were made by Dr. R. T. Gudauskas, Department of Botany and Microbiology.

Results from preliminary tests are shown in tables 18-20. If a hybrid is outstanding in these preliminary tests it is advanced to the regular testing program the following year.

When comparing hybrids, small differences in yield may not be real differences between hybrids but may result from variation in the plots and testing procedures. To aid in determining real differences between hybrids a statistical procedure, analysis of variance, was performed on data from each location. The L.S.D. (least significant difference) is given for yield at each location.

Long term averages are more reliable when choosing a hybrid for an area. Three-year results are considered sufficient to give a

good measure of the performance of hybrids. A composite rating system was used to determine the list of acceptable hybrids. The northern, central or southern Alabama regional average yield of a hybrid was used as its base point. The composite score was obtained by subtracting values for lodging, quality, and height of ears from its yield. The value subtracted for each characteristic was proportional to the numerical value shown for the characteristic in tables 2, 6, and 10. Although those hybrids that have a good record for 2 years in the regular test are included, and noted, on the acceptable list; when possible, data from 3 or more years are used in evaluating the hybrids

All of the acceptable hybrids are not equal in performance.

Some are outstanding in one or more characteristics. Others may not be outstanding in any one characteristic, but possess a satisfactory combination of characteristics. For these reasons, it is suggested that this report be carefully studied before choosing a corn hybrid to plant in 1976.

ACKNOWLEDGMENT

Appreciation is expressed to the following individuals who furnished information for this report: J. T. Eason, J. K. Boseck, R. A. Moore, W. A. Griffey, E. M. Evans, J. W. Langford, F. T. Glaze, L. A. Smith, J. A. Little, E. L. Carden, J. E. Barrett, Jr., and J. G. Starling.

A special thanks is expressed to Mr. Marvin Ruf and Mrs. Sally Bagwell, Research Data Analysis, for the computation and statistical analysis of the data in this report.

ACCEPTABLE HYBRIDS FOR 1976

All of the acceptable hybrids are not equal in performance. It is suggested that this report be carefully studied before choosing a hybrid. Hybrids are listed according to composite rating within group and yellow and white hybrids designated (Y) and (W) respectively.
