List of Acceptable Hybrids for 1981-----	43

Performance of Corn Hybrids in Alabama, 1980

Cliff G. Currier^{1/}

Corn hybrids are evaluated annually at 12 locations in the regular corn hybrid testing program of the Auburn University Agricultural Experiment Station. Preliminary tests are also conducted at one location in each region. Entries in preliminary tests are both experimental and newly released hybrids that have not been tested in the regular tests. If a hybrid is outstanding in the preliminary tests it is entered into the regular testing program the following year. White corn hybrids are tested at one location in each region.

Rainfall distribution was fair to poor depending on location during the 1980 growing season (table 1). Good yields were obtained at Fairhope, Brewton, Headland, and Prattville. Test yields at other locations averaged less than 60 bushels per acre. Generally, yield reduction was due to the lack of adequate rainfall during the period of greatest need for moisture by the hybrids in the tests. All data from the E.V. Smith Research Center, near Shorter, were not reported due to low and erratic yields.

Location of the tests, cultural practices, and average plant populations are shown in table 2. All hybrids at a location were treated the same. The experimental design was a randomized complete block with four replications. Row width was 36 to 40 inches depending on location. Two-row plots were used with row length varying from 18 to 30 feet depending on location. The target plant population for all tests was 20,000 plants per acre, with a seeding rate of 23,000 seeds per acre. The target plant

^{1/}

Research Associate, Department of Agronomy and Soils.

population for the irrigated test at Headland was 26,000 plants per acre, with a seeding rate of 30,000 seeds per acre. After thinning, most locations obtained the target plant population in all plots.

Grain yields were adjusted to 15.5 percent moisture and converted to bushels (56 pounds) per acre. Stalks broken or leaning more than 45 degrees were considered lodged. Ear rot, earworm damage, size, and color of grain were used in rating grain quality. Height of ears was measured from ground level to the base of the ear. Husks were rated according to tightness and extension beyond the tip of the ear. The mid-silk date measured the number of days from planting until one half of the plants in the plots were showing silks.

Regional averages for 3, 2, and 1 years in northern Alabama are presented in tables 3, 4, and 5, respectively. Table 6 shows yields by location, and regional average yields for 1 to 5 years in northern Alabama. Similar data are given for central Alabama in tables 7-10, and for southern Alabama in tables 11-14. Yields from the irrigated test at Headland were excellent. Two- and 1-year averages for the irrigated test are shown in tables 15 and 16, respectively. In 1980, approximately 1-inch of sprinkler irrigation water was applied on June 3, 8, 12, 17, July 5, 7, 10, 14, and 25. Approximately 9 inches of irrigation water was applied over this period of time. Data from the test at Marion Junction are given and should be used to assist in comparing hybrids grown in that area. Performance of corn hybrids at Marion Junction for 3, 2, and 1 years are given in tables 17, 18, and 19, respectively. Yields and other characteristics of white corn hybrids grown at Crossville and Headland are given in tables 20-21. Results of the preliminary tests are given tables 23-24. The 1980 results of the preliminary and white corn test grown at the E.V. Smith Research Center are not shown due to extremely low yields.

The corn hybrid tests are examined each year for viral and other disease symptoms by Dr. R. T. Gudauskas, Department of Botany, Plant Pathology, and Microbiology. When disease symptoms indicate that damage may occur, disease ratings are compiled and published in this report. An introduction and discussion of procedure and results are given. Virus infection data from the hybrid test at Marion Junction are given in table 22.

When comparing hybrids, small differences in yield may not be large enough to be considered real differences. To aid in determining real differences between yields a statistical procedure, analysis of variance, was performed on the data from each location. The L.S.D. (least significant difference) and C.V. (coefficient of variation) are given for yields at each location in 1980.

Since performance of hybrids may vary from year to year and location to location, long-term averages from several locations are more reliable than 1-year averages when evaluating a hybrid from an area. Three-year results are considered sufficient to give a good indication of the relative performance of hybrids.

A composite rating system was used to determine the list of acceptable hybrids. The 3-year regional average grain yield of a hybrid was used as a base point. Then, the composite score was obtained by subtracting weighted values for lodging, quality, and ear height from this yield. The value subtracted for each characteristic was proportional to the numerical values shown for the characteristics in tables 3, 7, and 11.

All acceptable hybrids are not equal in performance. Some are outstanding in one or more characteristics. Others may not be outstanding in any one characteristic, but possess a satisfactory combination of

characters. All information should be carefully considered when selecting a hybrid.

ACKNOWLEDGMENTS

Appreciation is expressed to the following people: W.H. Hearn and Mrs. Sally Bagwell, Research Data Analysis for the computation and summarization of the data in this report. R.T. Gudauskas, Department of Botany, Plant Pathology, and Microbiology for making virus ratings and the virus incidence table in this report. Ms. Sherrie Sheppard for typing this manuscript. The following cooperators in charge of their respective substations:

Tennessee Valley Substation, Belle Mina - W.B. Webster, Superintendent

Sand Mountain Substation, Crossville - J.T. Eason, Superintendent

Upper Coastal Plain Substation, Winfield - R.A. Moore, Jr., Superintendent

Black Belt Substation, Marion Junction - L.A. Smith, Superintendent

Experiment Field, Prattville - F.T. Glaze, Superintendent

E.V. Smith Research Center, Shorter - R. Akridge, Superintendent

Lower Coastal Plain Substation, Camden - J.A. Little, Superintendent

Piedmont Substation, Camp Hill - W.A. Griffey, Superintendent

Experiment Field, Brewton - J.A. Pitts, Superintendent

Experiment Field, Monroeville - J.A. Pitts, Superintendent

Gulf Coast Substation, Fairhope - E.L. Carden, Superintendent

Wiregrass Substation, Headland - J.G. Starling, Superintendent

VIRAL DISEASE REACTIONS OF SOME HYBRIDS IN 1980

Robert T. Gudauskas

Department of Botany, Plant Pathology,
and Microbiology

The two most prevalent viral diseases of corn in Alabama are maize chlorotic dwarf (MCD) caused by the maize chlorotic dwarf virus (MCDV), and maize dwarf mosaic (MDM) caused by the maize dwarf mosaic virus (MDMV). Discovery of MDM in the State dates back to the early 1960's, while MCD has been recognized only since 1973. Both diseases probably occur throughout Alabama, however, they generally have been more prevalent and damaging in the northern two-thirds of the State.

Symptoms of the two diseases are similar in appearance and sometimes difficult to distinguish. Generally, affected plants are chlorotic or discolored and may be stunted. Leaves of MDM-diseased plants show an irregular, light and dark green mosaic or mottle; the initial symptom of MCD is a fine, chlorotic streaking over the smallest veins.

The causal viruses are spread by feeding activities of insects. MCDV is transmitted by certain leafhoppers and MDMV is carried by some aphids. Both viruses have similar host ranges among a variety of wild and cultivated grasses. Johnsongrass is an important overseason or reservoir host for the viruses, and MCD and MDM incidence and damage usually are high in corn fields that are heavily infested with johnsongrass.

Use of resistant or tolerant corn hybrids presently is the most practical control of MCD and MDM. Commercial and experimental hybrids are evaluated yearly to identify resistant hybrids or promising sources of resistance to the diseases. Results of evaluations of some commercial hybrids during 1980 are summarized in this report.

PROCEDURE

Viral disease ratings were made on entries in the corn hybrid test at the Black Belt Substation, Marion Junction. Plants showing symptoms of MCD and/or MDM were counted and data are reported as percent incidence of viral diseases for each hybrid.

RESULTS

Evaluations for viral diseases in the hybrid test on the Black Belt Substation are given in table 22. Data given are total incidences of viral diseases. No attempt was made to separate MCD and MDM at the time of rating. However, MCD was clearly the predominant disease throughout the test. Tests on the Piedmont, Tennessee Valley, Sand Mountain, and Upper Coastal Plain substations were also examined, but disease incidence was insignificant.

The incidence of viral diseases ranged from 0-35% among the hybrids in the test and averaged 11.3% for the entire test. No symptoms of virus disease were found in Jacques JX227 and Paymaster UC9792, and disease incidence was less than 5% in several other hybrids.

Hybrids showing relatively greater resistance or tolerance were apparent. Under conditions of higher or lower incidence of viral diseases hybrids would be expected to retain their relative ranking. When selecting a hybrid, viral disease reactions should be taken into account for areas where the diseases occur, along with consideration of yield and other characteristics given elsewhere in this report.

1/Yields adjusted to 15.5% moisture and 56 lb. per bushel.

2/1 = excellent; 2 = good; 3 = fair; 4 = poor; 5 = very poor.

3/Check hybrids.

ACCEPTABLE HYBRIDS FOR 1981

All of the acceptable hybrids are not equal in performance. It is suggested that this report be carefully studied before choosing a hybrid. Hybrids are listed in descending order of their composite rating. For relative maturity information for these hybrids, use the number of days to midsilk, found in tables 5, 9, and 13. All hybrids have yellow grain except the white grain hybrids indicated by a (W).^{1/} All composite ratings are based on 1978-80 regional averages, found in tables 3, 7, and 11. All acceptable hybrids have been tested at least 3 years in the regular variety tests.
