List of Acceptable Hybrids for 1980-----	32

Performance of Grain Sorghum Hybrids in Alabama, 1980

Cliff Currier^{1/}

Introduction

Grain sorghum performance tests are conducted annually throughout Alabama by the Auburn University Agricultural Experiment Station. These tests give a relative comparison of hybrid performance under the conditions at a particular location. The performance of hybrids varies with location; therefore this report should be carefully studied before a hybrid is selected.

In 1980 tests were planted at seven locations. Test average grain yields of 70, 74, and 103 bu./A were obtained at Prattville, Monroeville, and Fairhope, respectively. Test average grain yields at other locations were less than 60 bu./A. Inadequate rainfall during the season was mainly responsible for reduced yields (table 1). Insect, bird, and disease damage was relatively light this year; although bird damage was high at Crossville. Only bird resistant hybrids were harvested at this location.

Experimental Procedures

Cultural practices were uniform for all hybrids within a given test. The experimental design for all tests was a randomized complete block with four replications. Plot sizes and cultural practices for each test are listed by location in tables 4, 6, 9, 12, 15, 18, and 21.

Sources of seed used in the tests are listed on pages 30 and 31.

Data

Yield

Grain yields are given in bushels per acre adjusted to 14% moisture

1/

Research Associate, Department of Agronomy and Soils

at 56 pounds per bushel. At all locations yields were calculated from the weight of grain obtained from harvesting the whole plot. Plots at Crossville, Prattville, Headland, Monroeville, and Fairhope were harvested with a plot combine. At Winfield and Marion Junction plots were hand harvested and heads threshed with a plot combine.

Grain Damage Estimate

Visual estimates of grain damage were made at most locations. Estimates of grain damage can be used to indicate the amount of grain loss caused by birds, insects, and diseases. When estimates of grain damage are not shown, no significant grain damage occurred at that location during the year(s) involved.

Bird damage can be a major problem on small field plantings. In selecting a hybrid, consideration should be given to bird populations present in relation to the size of area to be planted. If bird damage is anticipated, hybrids with low estimates of grain damage should be used. One should keep in mind that bird resistant grain sorghum hybrids are more difficult to market and have lower feeding value than non-bird resistant grain sorghum hybrids.

Lodging

Lodging is given as the percent of plants broken or leaning at an angle of more than 45 degrees from vertical. The seedheads of most lodged plants would be missed by a combine. However, the heads of lodged plants are included in the yields of hand harvested plots.

Plant Height

Plant height was measured from the soil surface at the base of the plant to the tip of the head.

Head Exsertion

Head exertion was measured from the collar of the flag leaf to the base of the head. Poor head exertion may result in excessive green plant material in the harvested grain, and may cause damage to the lower

part of the head resulting from water accumulating at the base of the flag leaf.

Head Type

Open or loose heads may be important in the Southeastern United States. Open heads allow better air movement and faster drying of rain or dew. Open heads may be helpful in reducing damage from insects and diseases which attack the heads. A rating of 1 for tight heads and 3 for open or loose heads was used at all locations.

Mid-Bloom

One measure of relative maturity is the mid-bloom date. This is the date when approximately one-half of the heads in the plot are in bloom (showing anthers). Date of mid-bloom for entries at all locations is shown in tables 4, 6, 9, 15, 18, and 21.

Mid-bloom data from Marion Junction are not shown due to erratic plant emergence.

Selecting a Hybrid

The performance of hybrids varies among years and locations. Small yield differences between hybrids may be the result of slight differences in soil fertility and other factors. To aid in determining real differences between hybrids, a statistical procedure, analysis of variance, was performed on the data from each location. The L.S.D. (least significant difference) is given to determine real differences between hybrid yields for each location in 1980. When comparing hybrids, the yield difference between two hybrids is compared to the L.S.D. value. If the yield difference is greater than the L.S.D. value, then the two hybrids are considered to be significantly different. The C.V., coefficient of variance, is a measure of uncontrolled variability within a test.

The list of acceptable hybrids is based on yield and lodging data.

Three-year averages are reviewed for each location. The acceptable hybrids list is tabulated by combining the location lists for each region. Since all acceptable hybrids are not equal in performance, a review of the data from several years at the testing location most similar to your situation is the most reliable method for selecting a hybrid best suited for your needs.

Acknowledgment

The performance trials were conducted in cooperation with the following substation and experiment field superintendents whose help is gratefully acknowledged: R.A. Moore, Upper Coastal Plain; J.T. Eason, Sand Mountain; L.A. Smith, Black Belt; J.A. Little, Lower Coastal Plain; J.G. Starling, Wiregrass; and E.L. Carden, Gulf Coast; (Substation) F.T. Glaze, Prattville; and J.A. Pitts, Monroeville; (Experiment Field). Thanks are expressed to W.H. Hearn and Mrs. Sally Bagwell for processing the data presented in this report. Appreciation is also expressed to Ms. Sherrie Sheppard for typing this report.

Test average: 103.3

L.S.D. (.05): 9.9

C.V. (%): 8.1

1/ Whole plot yields adjusted to 14% moisture and 56 lb. per bushel.

2/ Measured from terminal leaf to base of the head.

3/ 1 = tight; 2 = medium; 3 = loose.

Planted: April 23, 1980.

Plot size: 2 rows, 20 feet long, 36-inch row spacing.

Nitrogen Rate: 130 lb. (N/A), split application.

Herbicide: Milogard (Propazine).

ACCEPTABLE HYBRIDS FOR 1981

All of the acceptable hybrids are not equal in performance. It is suggested that this report be carefully studied before choosing a hybrid. Hybrids are listed in alphabetical order within bird resistant and non-bird resistant groups. The locations used in making regional lists are as follows: Winfield, Northern Alabama; Marion Junction and Prattville, Central Alabama; Headland, Monroeville, and Fairhope, Southern Alabama. For further information on hybrids see individual location tables. All acceptable hybrids have been tested 3 years at one or more locations within the region.

NORTHERN ALABAMA

^{1/}

If present trends continue, this hybrid will be removed from the acceptable list next year in the region indicated.

^{2/}Performance of hybrids in the Black Belt may be different from other areas of Central Alabama. For performance of hybrids in the Black Belt, see Tables 10, 11, and 12.

^{3/}Bird resistant hybrids may be difficult to market, and also have lower feeding value than non-bird resistant hybrids.
