## 1980 ALABAMA COTTON VARIETY REPORT<sup>1/</sup>

A Report of the Performance of Cotton Varieties  
Tested at Nine Locations in Alabama During 1980

Wiley C. Johnson<sup>2/</sup>

The Alabama Cotton Variety Test is a continuing evaluation of available cotton varieties from private companies and state agricultural experiment stations. Breeding lines that are likely to be released as varieties are also tested. Tests are conducted on units of the Agricultural Experiment Station by Experiment Station personnel. Cultural practices are as generally recommended by Auburn University to farmers. Every effort is made to test the varieties and present the data in an unbiased manner.

### Experimental Conditions

A randomized block experimental design with four replications was used at each location. Plot row length at different locations varied from 34.5 to 100 feet. Plots were two-row at Prattville, Headland, Belle Mina, and Crossville. Single row plots were used at the other locations. Cotton was planted during the optimum planting period at each location. Rainfall was adequate early in the season but deficient during July and August at most locations in 1980. The drouth was most severe at Winfield and at the E.V. Smith Research Center near Shorter (Macon County). July and August temperatures were considerably above normal throughout Alabama. Insect control was generally adequate.

<sup>2/</sup>Professor, Department of Agronomy and Soils

Explanation of Data

Harvest of Seed Cotton: Tests at Prattville, Brewton, Monroeville, Tallassee, and Belle Mina were harvested by a mechanical spindle picker. Tests at Winfield, Headland, Shorter, and Crossville were harvested by hand. Average yield of seed cotton was determined for each variety at each location.

Lint Percentage: A sample of seed cotton from each variety at each location was taken at harvest and ginned on a 10-saw gin. Lint percentage was calculated by dividing weight of lint by weight of seed cotton.

Yield of Lint: Lint yield was determined by multiplying the lint percentage by yield of seed cotton.

Fiber Properties: Because of the time required for the detailed determinations of the fiber properties, data presented in the current report are from 1979 samples. Fiber qualities were determined by the USDA Cotton Quality Spinning Laboratory, Knoxville, Tennessee.

(a) Span length: This is the fiber length measured on the digital fibrograph. The figure given is the distance spanned by 2.5% of the fibers, where the initial point of scanning is 100%. This length, in inches, approximates classer's staple.

(b) Stelometer:  $T_1$  is a measure of breaking strength of a standard fiber bundle with the holding jaws separated by 1/8 inch. This is a metric measurement similar to Pressley strength except the figures are in centinewtons per tex. A centinewton is a measure of force and a tex is a size measurement of the fibers. The larger the  $T_1$ , the stronger the fibers.  $E_1$  measures the percentage stretch before the fibers break.

(c) Micronaire: This measures the fineness and maturity of the cotton fibers. The smaller the micronaire reading, the finer and/or more immature the fibers. The desirable range of micronaire is 3.5 - 4.9.

Earliness: Where more than one harvest was made, earliness is reported as the percentage of the total yield harvested at the first picking.

Fusarium wilt: Reaction of varieties to Fusarium wilt was evaluated at the Plant Breeding Unit, Tallassee, by growing the varieties in fields with a high natural incidence of the fusarium wilt-root-knot nematode complex. Severity of the disease varies from year to year and also within the experimental area in the same year. Therefore, several years' data are necessary to realistically characterize a variety's wilt reaction. Stoneville 213, Hancock, Stoneville 825, and Vail 7 have consistently shown a high incidence of wilt. All other reported varieties that have been tested for at least 3 years have acceptable tolerance to furasium wilt.

#### New and Experimental Varieties

GaCot 79 is a frego bract cotton released in 1979 by the Georgia Agricultural Experiment Station and was first tested statewide in Alabama in 1980. Stoneville 506 is a recent release by the Stoneville Pedigreed Seed Co. It also was first tested throughout Alabama in 1980. Seed will be available for 1981 in very limited quantities. Coker 3113 was first entered for testing in 1980 as an experimental line. It has recently been released by the Coker's Pedigreed Seed Co. and named Coker 3131. GP 3774 and GP 3755 are early varieties from Texas developed and released by the G and P Seed Co. Delcot 311 was developed by the

Missouri Agricultural Experiment Station and released in 1980. This is the first year it has been tested in Alabama.

Deltapine 7148 and Coker 3114 are experimental lines of Delta and Pine Land Co. and Coker's Pedigreed Seed Co., respectively. It is the policy of the Auburn University Agricultural Experiment Station to evaluate a limited number of such experimental lines as a service to plant breeders and also to test potential varieties prior to their release.

Paymaster 303 and Acala SJ-5 are varieties adapted to the western areas of cotton production and are included in certain Alabama variety tests as national standard varieties.

#### Statistical Analysis

Appropriate analyses of the yield data were made. For each location, the variability in the test was calculated and expressed as a percentage of the test mean, coefficient of variation (C.V.). An indication of the difference between variety averages necessary to be a real difference is given for each location, Least Significant Difference (L.S.D..05).
