PERFORMANCE OF CORN HYBRIDS IN ALABAMA, 1983

W. C. Johnson and Darrell Williams¹

INTRODUCTION

Corn hybrids are evaluated annually by the Alabama Agricultural Experiment Station in the Regular Corn Hybrid Test and the Preliminary Corn Test on a north, central, and southern regional basis. The Marion Junction, or Black Belt Substation, corn test is used as the prairie soil regional comparison. Entries in the preliminary tests are both experimental and newly released hybrids. If a hybrid is outstanding in the preliminary test, it is entered into the regular corn test the following year. White corn hybrids are tested at one location in each region. One regular and one white corn hybrid test are irrigated at Headland in southern Alabama.

The locations and cultural practices for the tests are shown in Table 1.

The tests were designed as a randomized complete block with four replications. Row width was 36 to 40 inches depending on location. Two-row plots were used with row length ranging from 20-30 feet depending, again, on location. The target plant population for the tests was 20,000 plants per acre with a seeding rate of 23,000 seeds per acre. The irrigated tests at Headland were seeded at a rate of 30,000 plants per acre and thinned to 26,000.

Grain yields were adjusted to 15.5 percent moisture and converted to bushels (56 pounds) per acre. Stalks broken or leaning more than 45 degrees were considered lodged. The mid-silk data measured the number

¹Professor and Technical Assistant, Department of Agronomy and Soils.

of days from planting until one-half of the plants in the plots were showing silks.

Bushel test weights are reported as regional averages from this year's data. All test weight values were adjusted to 15.5 percent moisture to make comparisons easier.

The corn hybrid tests are examined for disease incidence each year by Dr. R. T. Gudauskas, Department of Botany, Plant Pathology, and Microbiology. When virus or other disease symptoms indicate crop damage, disease ratings are compiled and published in this report. Virus infection data from the test at Marion Junction are reported this year.

To aid in determining real yield differences, a statistical analysis of variance is performed on the data from each location. The L.S.D. (least significant difference) and C.V. (coefficient of variation) are given for each location's 1983 test. The difference in yield of two hybrids must exceed the L.S.D. value for one hybrid to be considered superior to the others in yield in that particular test. The C.V. is a measure of the variability in an experiment. An increase in its value indicates an increase in the unaccounted for variability.

Since the performance of hybrids varies with location and year, long-term averages from several locations are more reliable than 1-year performance. Three-year regional averages are considered a reliable evaluation of the relative performance of hybrids.

A composite rating system was used to assemble a list of acceptable hybrids. The 3-year regional average grain yield was used as a base point. The composite score was obtained by subtracting weighted values for lodging, quality, and ear height from the yield.

The recommended hybrids are not all equal in performance. Some are outstanding in one or more characteristics; while others may not be obviously outstanding, they might possess a satisfactory combination of all characteristics.

ACKNOWLEDGMENTS

Appreciation is expressed to the following station superintendents and their staffs. It is their quality work which makes this a reliable source of information for farmers in their areas.

Northern Alabama

Tennessee Valley Substation, Belle Mina - W. B. Webster

Sand Mountain Substation, Crossville - J. T. Eason

Upper Coastal Plain Substation, Winfield - R. A. Moore, Jr.

Central Alabama

Black Belt Substation, Marion Junction - L. A. Smith

Prattville Experiment Field - D. P. Moore

E. V. Smith Research Center, Shorter - J. R. Akridge

Southern Alabama

Brewton Experiment Field - J. A. Pitts

Monroeville Experiment Field - J. A. Pitts

Gulf Coast Substation, Fairhope - E. L. Carden

Wiregrass Substation, Headland - J. G. Starling

Appreciation is also expressed to the following people:

W. H. Hearn and Mrs. Sally Bagwell, Research Data Analysis, for the computation, summarization, and analysis of the data in this report,

R. T. Gudauskas, Department of Botany, Plant Pathology, and

Microbiology, for making virus ratings and the virus disease reactions in this report, and Ms. Mary Ann Taylor, Department of Agronomy and Soils, for the coordination of this report.

VIRAL DISEASE REACTIONS OF SOME HYBRIDS IN 1983²

The two most prevalent viral diseases of corn in Alabama are maize chlorotic dwarf (MCD), caused by the maize chlorotic dwarf virus (MCDV), and maize dwarf mosaic (MDM), caused by the maize dwarf mosaic virus (MDMV). Discovery of MDM in the State dates back to the early 1960's, while MCD has been recognized only since 1973. Both diseases probably occur throughout Alabama; however, they generally have been more prevalent and damaging in the northern two-thirds of the State.

Symptoms of the two diseases are similar in appearance and sometimes difficult to distinguish. Generally, affected plants are chlorotic or discolored and may be stunted. Leaves of MDM-diseased plants show an irregular, light and dark green mosaic or mottle; the initial symptom of MCD is a fine, chlorotic streaking over the smallest veins.

The causal viruses are spread by feeding activities of insects. MCDV is transmitted by certain leafhoppers, and MDMV is carried by some aphids. Both viruses have similar host ranges among a variety of wild and cultivated grasses. Johnsongrass is an important overseason or reservoir host for the viruses, and MCD and MDM incidence and damage usually are high in corn fields that are heavily infested with johnsongrass.

Use of resistant or tolerant corn hybrids and the control or avoidance of johnsongrass infested areas are the most practical controls for MCD and MDM. Commercial and experimental hybrids are evaluated yearly to identify resistant hybrids or promising sources of resistance

²Prepared by Robert T. Gudauskas, Department of Botany, Plant Pathology, and Microbiology.

to the diseases. Results of evaluations of some commercial hybrids during 1983 are summarized in this report.

Procedure

Viral disease ratings were made on entries in the corn hybrid test at the Black Belt Substation, Marion Junction. Plants showing symptoms of MCD and/or MDM were counted and data are reported as percent incidence of the diseases for each hybrid.

Results

At the Black Belt Substation (Table 30), incidence of MDM ranged from 0-16 percent among hybrids and averaged 4.9 percent for the entire test; incidence of MCD ranged from 0-14 percent and averaged 3.6 percent for the test. McCurdy brands 81-34 and 7978, and Northrup King brand PX95 showed no symptoms of either disease, and incidence of either disease was less than 5 percent in at least 11 other hybrids.

Hybrids showing relatively greater resistance or tolerance were apparent. Under conditions of higher or lower incidence of viral disease, hybrids would be expected to retain their relative ranking. When selecting a hybrid, viral disease reactions should be taken into account for areas where the diseases are known or suspected to occur, along with considerations of yield and other characteristics given elsewhere in this report.

ACCEPTABLE HYBRIDS FOR 1984

All of the acceptable hybrids are not equal in performance. It is suggested that this report be carefully studied before choosing a hybrid. For relative maturity information, use the days to mid silk data in Tables 4, 8, and 11. All acceptable hybrids on this page have been tested at least 3 years in the regular variety tests and are listed in descending order of 3-year average yield for each region.
