Performance of Ryegrass Varieties in Alabama, 1996-97

KATHRYN M. GLASS AND DAVID I. BRANSBY

The Alabama Ryegrass Variety Evaluation is a continuing study of available varieties and breeding lines from private companies and state agricultural experiment stations. Experiments are planted annually in northern, central, and southern locations to evaluate the varieties and lines under the different environmental conditions of Alabama. Entries in each experiment are determined by the companies or institutes which control each variety, or line, not by experiment station personnel. The experiments are conducted by experiment station personnel and the results are presented in a fair and unbiased manner.

EXPERIMENTAL PROCEDURES AND DISCUSSION

Ryegrass entries were seeded at a 20-pound-per-acre rate in rows seven inches apart, using 5x20-foot plots with four replications. Good stands were obtained at the following locations: Sand Mountain Substation in Crossville and E.V. Smith Research Center Plant Breeding Unit in Talladega. A less than adequate stand was obtained at Gulf Coast Substation in Fairhope.

The experiments were fertilized with phosphorus and potassium according to Auburn University soil test recommendations. At planting, nitrogen was applied at the rate of 50 pounds per acre, and an additional 50 pounds of N per acre was applied after each cutting. A 32- or 49-inch swath of each plot was harvested to a cutting height of 1.5 to two inches with a flail harvester each time the ryegrass reached six to 10 inches tall. A herbage sample of approximately one pound was taken from each plot at each harvest for determining forage dry matter percentage.

In 1995, the tests were planted Sept. 29, Sept. 28, and Oct. 11 at Crossville, Talladega, and Fairhope, respectively. Cooler than normal temperatures greatly reduced fall and winter growth at all locations. In 1996, the tests were planted Oct. 7, Oct. 17, and Oct. 15 at Crossville, Talladega, and Fairhope, respectively. Good stands were obtained at Crossville and Talladega. Less than adequate planting conditions reduced stands and yields at Fairhope. All locations had wet conditions, but normal growth occurred on most varieties.

Strategies to meet seasonal forage needs are an important consideration for livestock producers. Tables 1-3 provide yield data by harvest for 1996-97 at a given location, while Table 4 shows one-, two-, and three-year total yields by location. Seasonal and total forage dry matter yields by locations are provided in Table 5. The three seasonal periods are: fall-forage produced through February; early spring-March and early April production; and late spring-production after April 20. A three-year average provides a more dependable comparison of ryegrass varieties than do single-year results.

ACKNOWLEDGMENTS

Appreciation is expressed to Mien-Huei Tzeng, Research Data Analysis, for the data processing of this report. Also acknowledged are the contributions of Tony Dawkins and Marvin Ruf, Sand Mountain Substation; Ronnie McDaniel and Malcomb Pegues, Gulf Coast Substation; and Jim Bannon and Stevan Nightengale, E.V. Smith Research Center, for growing and harvesting the experiments.

Location of Participating Research Units

Ryegrass variety trials were conducted at three AAES substations: Gulf Coast Substation (GCS) in Fairhope, the E.V. Smith Research Center Plant Breeding Unit (EVSRC) in Tallahassee, and Sand Mountain Substation (SMS) in Crossville. Without the commitment of the substation personnel, results presented in this report would not have been presented in a timely manner.
