

PROJECT PREDICTION PROGRAM

& STATISTICS FOR ALABAMA

**ENVIRONMENTAL STUDIES SERVICE CENTER SPECIAL REPORT
AGRICULTURAL EXPERIMENT STATION AUBURN UNIVERSITY
R. DENNIS ROUSE, DIRECTOR AUBURN, ALABAMA
NOVEMBER 1979 WEATHER SERIES NO. 18**

SUMMARY

Tables of precipitation averages, extremes, and probabilities of selected precipitation amounts are presented for 30 Alabama locations. The probabilities were calculated by the incomplete gamma distribution technique. Suggested applications for agriculture, water resources, and other outdoor activities are described.

PRECIPITATION PROBABILITIES AND STATISTICS
FOR ALABAMA

RODGER R. GETZ¹ AND LARRY M. OWSLEY²

INTRODUCTION

Variability of precipitation is a determining factor in agricultural production. Crop growth, yields, and irrigation needs are influenced by amount, duration, timeliness, and reliability of precipitation. Outdoor activities such as construction, painting, and recreation can be hampered by precipitation. Knowledge of the normal variability of precipitation allows for planning such activities to take advantage of dry or wet periods.

Presented in this publication are tables of average total precipitation, extreme total precipitation, and probabilities of exceeding selected precipitation amounts during 1-, 2- and 3-week periods. The analysis was done with 25 or more years of data for 30 Alabama stations.

It should be noted the precipitation probabilities given in this publication cannot be used as a forecast of future precipitation events and should not be confused with probability forecasts given in daily weather forecasts. The probabilities given here are useful for long-range management planning and for comparing recent precipitation events with the long-term statistics.

PREVIOUS WORK

Precipitation probability studies have been conducted in nearly every state. Cope et al. (2) prepared graphs of rainfall distribution by 10-day

¹/ Agricultural Meteorologists, National Weather Service, Environmental Studies Service Center.

²/ Computer Programmer, Research Data Analysis.

periods for Alabama. Monthly precipitation probabilities have been calculated for the eight climatological divisions of Alabama by Strommen and Horsfield (12). Other unpublished probability studies for Alabama have been prepared by the Environmental Data Service (7).

The most widely used model for determining precipitation probabilities is the incomplete gamma distribution. Barger and Thom (1) found that this model appropriately smooths out irregularities of probability curves for weekly, monthly, or seasonal amounts. There are numerous examples applying the incomplete gamma distribution model to precipitation data including analyses done by Crosby et al. (3) for Georgia, Dethier, and McGuire (6) for the Northeast United States and Shaw et al. (11) for the North Central United States. A complete description of the incomplete gamma distribution can be found in most advanced statistics texts.

PROCEDURE

Thirty stations were selected for the analysis. These stations had continuous precipitation data for a minimum of 25 years. Four stations had over 70 years of record. A good geographical distribution was achieved. Table I lists the stations used and figure 1 shows their location.

Daily precipitation records for the 30 stations were extracted from computer tapes prepared by the National Climatic Center (NCC), Asheville, North Carolina. The tapes contained official data as published by NCC in the Alabama Climatological Data Series (8). Eleven stations had additional data not encoded on the tapes. These additional data were extracted from hardcopy published records (from the Alabama Climatological Data Series), key punched, and put in the same format as the computer tape data. The full data series was then checked for completeness, extreme values, and invalid coding. Any invalid data was set to "99.99" to indicate a missing observation.

The data were then summarized into weekly totals by climatic week. Climatic weeks were used to allow comparisons with other climatological studies

and to smooth out variabilities in the daily data series. Weeks with 3 or more days of missing data were shown as missing for the entire week. Where 1 or 2 days of data were missing, these days were set to zero and the weekly total computed. Data for February 28 and 29 (climatic week 53) were omitted.

The data were then ready for input into the incomplete gamma distribution model using computer programs written by Crutcher et al. (4, 5). The program computed the mean total, maximum total, probability of exceeding selected precipitation amounts for 1, 2, and 3 climatic week periods and other statistical parameters.

All programs were run on the Auburn University IBM 370/158 computer.

RESULTS AND DISCUSSION

Tables 2 through 31 list selected precipitation statistics and probability data for the 30 stations. Separate tables are given for the 1-, 2-, and 3-week summary periods and are denoted in the tables with the letters "a", "b" and "c" respectively.

Using table 2a as an example, each table can be interpreted as follows. The top of the table shows that Andalusia had data for the period January 1938 through December 1974 for summarization and analysis by 1-week periods. The average total precipitation for the period March 1-7 is 1.81 inches with the greatest weekly total being 7.30 inches. (It should be noted that higher maximum totals are possible in weeks that were not included in the analyses due to missing data.) There is an 86.5 percent probability that Andalusia will have measurable rain during the first week of March with the probability of getting more than 1 inch of rain being 57.5 percent. The driest week of the year at Andalusia is October 11-17 when the probability of receiving measurable precipitation is only 41.2 percent.

The precipitation amounts and accompanying probabilities given are over 1-, 2-, and 3-week periods. Rain may occur at any time during each period. Therefore, one can not determine from the tables the number of rain days or storm events.

SUGGESTED APPLICATIONS

Tables 2 through 31 can be used as an aid for long-range plans such as crop scheduling, determining critical times for irrigation, water resource planning, finding favorable periods for outdoor recreation and other activities. The analysis for each station should be representative of other locations in the same county. Extrapolation to locations in other counties is feasible when local topographic influences are minor.

Crop Scheduling

Adequate moisture for germination of seed can be a problem for some Alabama crops. Germination rates during drier weather can often be improved by increasing the seeding rate. A more critical time for adequate moisture is usually during the period of vegetative growth for shallow-rooted vegetative crops and during the flowering and fruit-set stage for deep-rooted fruiting crops (Hilgeman and Pew, 9). Decreased chances of rain are desired at harvest time for most crops. Examples for three major Alabama crops are given below.

Soybeans

The pod filling stage is a time of critical water need for soybeans. This period is usually from mid-August through mid-September in Alabama. Using table 14a for Fairhope, soybeans planted to reach pod filling during the period August 16-22 or August 30-September 5 have a greater chance of receiving 1 inch or more of rain (58.4 percent and 50.6 percent, respectively). August 23-29 has only a 39.4 percent chance of exceeding 1 inch of rain.

Irrigation/Water Resource Planning

A frequent "rule of thumb" for irrigation scheduling described by Rubey (10) calls for a water demand of 1 inch per week for vegetable crops. Madison county growers can see from table 18a that they have less than a 50 percent chance of receiving more than 1 inch of rain each week during most of the growing season. As shown in table 7a, Brewton area farmers can count on natural rainfall to provide more than 1 inch of rain on many weeks throughout the growing season.

Extreme precipitation events are important for water resource planning. Water systems, storm sewers, roof drains, flood control structures, and other structures are designed to meet certain possible precipitation extremes. Mobile (table 20a) has a greater chance of receiving more than 4 inches of precipitation in a week than any of the other 29 stations. However, the probabilities of more than 10 inches are low for Mobile.

Another source of extreme precipitation statistics is the maximum total listed for each station. Using table 20a for Mobile again, the maximum 1 week precipitation total (over the year 1949-73) was 13.36 inches during the week of April 12-18.

Other Outdoor Activities

The timeliness and amount of precipitation is important for planning other outdoor activities. A contractor may not want any rain while replacing a roof. The column listing the probability of getting any precipitation (shown as 0.00 in the tables) would be useful in this determination. Concrete work may be able to receive up to a tenth of an inch of precipitation without halting work. The tables can also be used to find favorable periods for haymaking. The 1-week probabilities for exceeding a quarter inch may apply for this outdoor activity.

ACKNOWLEDGMENT

The cooperation and support of D. R. "Shorty" Davis, former ESSC Director, and Dr. Richard Patterson, Head of Research Data Analysis is appreciated. Numerous College Work-Study students aided in the data extraction and quality control. Mrs. Brenda Robbins also helped with the data extraction and typed the manuscript.

Soybeans in Alabama are usually harvested in October. Dry weather is preferred by soybeans growers for optimum harvesting quality and for reduced need for artificial drying. Using table 14c, the most favorable harvest weather for soybeans in the Fairhope area is in late October (October 11-13) when the probability of measurable precipitation is at the lowest for the 3-week period.

Corn

June is a critical time for Alabama corn. Adequate moisture is needed for the silking and tasseling stage. Production losses are possible if soil moisture is inadequate. Using Crossville as an example (see table 12a), corn planted to reach silking and tasseling during the week of June 21-17 has the greatest chance of benefiting from 1-inch or more (42.8 percent probability) of rain. There is also a 16.9 percent chance of exceeding 2 inches of rain during this week.

Wet weather is not desirable at harvest. Optimum harvest weather for corn can be selected from the tables in a similar manner as shown for soybeans.

Peanuts

A good supply of moisture is needed during July when Alabama peanuts are flowering and pegging. Table 13a (Dothan) shows there is at least 50 percent chance of getting over 1 inch of rain per week in July with rain most likely July 19-25.

Peanut digging, windrow curing, and combining requires 3 to as much as 10 days of dry weather. Table 13c, shows that the 3-week period October 11-31 is the driest with table 13b, indicating the 2-week period October 11-24 has the lowest chance of more than 2 inches of rain over the entire year.
