PERFORMANCE OF RYEGRASS VARIETIES

IN ALABAMA, 1984

W. C. Johnson and Darrell Williams,¹

The Alabama Ryegrass Variety Test is a continuing evaluation of available varieties and breeding lines from private companies and state agricultural experiment stations. Tests are planted in three locations, northern, central, and southern, to evaluate the varieties under the different environmental conditions of these regions of Alabama. The tests are conducted by experiment station personnel and the results presented in a fair and unbiased manner.

Experimental Procedure and Discussion

Ryegrass entries were seeded at a 20-pound-per-acre rate in rows 6 inches apart, using plots 4 x 20 feet with four replications. A good stand was obtained at each location after the late-September 1983 planting dates. The extremely cold December and January weather restricted winter growth, but all varieties at all locations survived and produced well in the spring.

The tests were fertilized with phosphorus and potassium according to soil test. At planting, nitrogen was applied at the rate of 50 pounds N per acre. An additional 50 pounds of N was applied per acre after each cutting to allow the varieties to perform at their maximum yield

¹Professor and Research Associate, Department of Agronomy and Soils.

potential. The plots were harvested when the ryegrass reached 6-10 inches with a flail type harvester to a 2-inch stubble. A herbage sample of approximately 1 pound was taken from each plot at each harvest for determining forage dry matter percentage, for converting green weights to dry matter.

The Plant Breeding Unit at Tallassee, despite extremely cold weather, produced excellent yields of forage. The ryegrass was cut nine times, with the test's average yield of all entries being almost 5 tons of dry forage.

Marshall continued to be among the highest in total herbage production throughout Alabama and is especially outstanding in late winter/early spring production. Urbana, a variety entered by Van Der Have Seeds of the Netherlands and tested in Alabama for the second year, shows similiar yield capability to Marshall at all three test locations. Marshall's and Urbana's consistent high ranking shows their productive ability under most Alabama conditions.

Planning ways to meet seasonal forage needs is an important consideration for cattle producers. Tables 7, 8, and 9 show 3-year average seasonal distribution of forage for the varieties tested. Autumn yield at the Gulf Coast Substation is often restricted by low rainfall, but is compensated for by high production during the mild, moist winter. Little or no forage production can be expected during the usually severe winter in the Sand Mountain area of northern Alabama.

ACKNOWLEDGMENTS

Appreciation is expressed to W. H. Hearn and Mrs. Sally Bagwell, Research Data Analysis, for the data processing of this report. We also acknowledge the contributions of E. L. Carden, Larry Wells, and N. R. McDaniel, Gulf Coast Substation, J. T. Eason and M. E. Ruf, Sand Mountain Substation, and L. L. Walker, Plant Breeding Unit, for growing and harvesting the experiments.
