Information contained herein is available to all persons regardless of race, color, sex, or national origin.

ACKNOWLEDGMENTS

The performance trials were conducted in cooperation with the following substation and experiment field superintendents and their staffs whose quality work makes this report a reliable source of information for farmers in their areas.

Northern Alabama

Tennessee Valley Substation, Belle Mina - W. B. Webster,

H. E. Burgess,

B. E. Norris

Upper Coastal Plain Substation, Winfield - W. A. Griffey,

R. C. Rawls

Central Alabama

Black Belt Substation, Marion Junction - J. L. Holliman, J. R. Harris

Southern Alabama

Monroeville Experiment Field, Monroeville - J. R. Akridge

Appreciation is also expressed to Mien-Huei Tzeng, Research Data Analysis, for the computation, summarization, and analysis of the data in this report.

EVALUATION OF GRAIN SORGHUM HYBRIDS IN ALABAMA, 1992 K.M. Glass and D.I. Bransby¹

INTRODUCTION

Grain sorghum performance tests are conducted annually throughout Alabama by the Alabama Agricultural Experiment Station. The test locations in 1992 were two in north, one in central, and one in south Alabama. The four locations used represent major soil and climatic areas of the State. Since the yield of hybrids varies with location, this report should be carefully studied before a hybrid is selected.

EXPERIMENTAL PROCEDURES

Cultural practices were uniform for all hybrids within a given test. The experimental design for all tests was a randomized complete block with four replications. Tests plots consisted of two rows 36 inches apart, 20 or 30 feet in length. The target plant population was 60,000 plants per acre, with a seeding rate 25 percent higher than normal to ensure a good stand. Test cultural practices are listed in table 1.

Grain yields were obtained by harvesting the whole test plot with a plot combine, and adjusting harvested grain weight and moisture to a standard 14 percent moisture and 56 pounds per bushel.

Lodging is given as the percentage of plants broken or leaning at an angle of more than 45 degrees. The seedheads of lodged plants were not included in the yields reported.

Time (days) to mid-bloom is one measure of relative maturity.

¹Research Assistant and Professor of Agronomy and Soils.

This is taken as the number of days from planting to the date when approximately one-half of the heads in the plot are in bloom.

Bird damage has been very heavy at many locations in recent years. In 1992 grain sorghum hybrids were evaluated at only four locations, and bird control noise devices were used to help keep bird damage to a minimum at each test location. There was considerable bird damage at the Tennessee Valley Substation (Belle Mina) in 1992. The test was discarded at this location in 1990 and also in 1991 because of severe bird damage, despite the use of a bird alarm. Bird damage, which can be a problem in small fields, was lower at the remaining locations in 1992. In selecting a hybrid, consideration should be given to bird populations; if damage is anticipated, bird-resistant hybrids should be used. However, bird-resistant grain sorghum hybrids are sometimes difficult to market and may have lower feed value than the non-bird-resistant hybrids.

VARIETY COMPARISONS

The performance of hybrids varies among years and locations.

Small yield differences among hybrids may be the result of slight environmental or cultural differences rather than real differences in yield potential among hybrids. To aid in determining real differences, a statistical analysis of variance was performed on the data from each location. The L.S.D. (least significant difference) at the 5 percent level is reported to help determine real differences between hybrid yields for each location. If the yield difference between two varieties at a given location is greater than the L.S.D. value, the two hybrids are considered to be significantly different in yield. The C.V.

(coefficient of variation) is a measure of test variability. An increase in its value indicates a decrease in the precision and reliability of the test data.

The list of acceptable hybrids is based on 3-year-average grain yield and lodging data. The list is divided into three regions; north, central, and south. Since all acceptable hybrids are not equal in performance, a review of the data from several years at the test location most similar to a particular situation is the most reliable method for selecting a hybrid best suited for those particular farming seeds.

Anthracnose can be a problem in sorghum fields. There were sporadic outbreaks of this disease in 1987, but little evidence of it since then. However, in years prior to 1987, grain sorghum in many northeast and west-central Alabama counties was devastated by anthracnose. Some fields yielded 50 to 75 percent less grain than expected. Feed quality of much of the harvest grain from diseased fields also was poor. Resistant grain sorghum hybrids have been the best defense against anthracnose. Of available adapted grain sorghum hybrids, Deltapine G-1711 and Pioneer Brand 8333 have the best resistance to this disease. Other hybrids with some anthracnose resistance are Dekalb DK-64 and Pioneer Brand 8222. Good management plus the use of disease-resistant grain sorghum hybrids are necessary to reduce losses to anthracnose.

There was not a second or ratoon crop of sorghum in 1990, 1991, or 1992 at any location. Plant height of grain sorghum hybrids is reported as location averages, table 6.

Table 1. Locations and Cultural Practices for the 1992 Grain Sorghum Hybrid Tests

| Location | Planting date | Nitrogen ¹ rate | Plant population | Harvest date | Herbicide | Insecticides |
|---|------------------|-------------------------------|---------------------|-----------------|-----------|--------------|

^{*} Bird-Resistant Hybrid.

Note: The test at this location was severely damaged by birds in 1992. This damage is reflected in the superiority of the bird resistant varieties and the unacceptably high CV. Therefore, results should be viewed with caution.

ACCEPTABLE HYBRIDS FOR 1993

All acceptable hybrids have been tested for 3 consecutive years in the region listed. All of the acceptable hybrids are not equal in performance. It is suggested that this report be carefully studied before choosing a hybrid. The hybrids are listed in descending order of 3-year-average yield for each region.
