Information contained herein is available to all persons regardless of race, color, sex, or national origin.

Issued in furtherance of Cooperative Extension work in agriculture and home economic, Acts of May 8, and June 30, 1914, and other related acts, in cooperation with the U.S. department of Agriculture. The Alabama Cooperative Extension System (Alabama A&M University and Auburn University) offers educational programs, materials, and equal opportunityemployment to all people without regard to race, color, national origin, religion, sex, age, veteran status, or disability

2003 ALABAMA COTTON VARIETY REPORT

K. M. Glass, C. D. Monks, C. H. Burmester, and Edzard van Santen

Agricultural Program Associate, Associate Professor and Extension Cotton & Soybean Specialist,
Extension Agronomist, and Professor

INTRODUCTION

The Alabama Cotton Variety Test is a continuing evaluation of available cotton varieties from private companies and state agricultural experiment stations. Breeding lines that are likely to be released as varieties are also tested. Tests are conducted on units of the Alabama Agricultural Experiment Station by Experiment Station personnel. Cultural practices are those generally recommended by the Alabama Cooperative Extension System to producers. Data are reported on irrigated tests at Belle Mina and Headland. No other tests received scheduled supplemental irrigation. Every effort is made to test the varieties and present the results in an unbiased manner.

EXPERIMENTAL CONDITIONS

Tests were split into early season and full season varieties. The maturity category for each variety was chosen by the company or cooperator. Deltapine NuCotn 33B and Sure-Grow 747 were included in both early and full season tests for comparison. Plot size was two rows at Prattville, Headland, Belle Mina, Shorter, and Fairhope. Row length varied at different locations from 20 to 120 feet. A randomized complete block design with four replications was used in all tests. The trial at Fairhope is not reported due to unfavorable weather conditions at harvest.

Cotton varieties were evaluated in a producer's field on a sandy loam soil in south Alabama naturally infested with reniform nematode (*Rotylenchulus reniformis*), continuously cropped in cotton by Dr. Kathy McLean of the Dept. of Entomology and Plant Pathology at Auburn University. All varieties were evaluated with and without the use of a chemical nematicide to give an indication of possible tolerance to reniform nematodes. Results are listed in tables 25 and 26 beginning on page 32.

EXPLANATION OF DATA

HARVEST OF SEED COTTON

A 50-boll sample was taken by hand for ginning, then test plots were harvested by a mechanical spindle picker at all locations. Average seed cotton yield was determined for each variety at each location.

LINT PERCENTAGE

Seed cotton samples from each variety were ginned on a 10-saw gin. Lint percentage was calculated by dividing weight of lint by seed cotton weight.

YIELD OF LINT

Lint yield was determined by multiplying the lint percentage by seed cotton yield.

FIBER PROPERTIES

Fiber qualities of all varieties were measured by the USDA-AMS Classing Office in Birmingham, Alabama using High Volume Instrumentation (HVI). Data are reported on a single composite sample of each variety from each location including the regional tests at Shorter and Belle Mina.

Micronaire: This measures the fineness of the cotton fibers. The smaller the micronaire reading, the finer and/or more immature the fibers.

Length: This is the fiber length measured with the HVI instrument. This measurement of length is similar to the classer's staple.

Strength: This is a measure of breaking strength of a standard fiber bundle with the holding jaws separated by 1/8 inch. "Tex" is a size measurement of the fiber bundle and the data given are the force in grams needed to break this bundle.

Uniformity: This is the ratio between the mean length and the upper half mean length of the fibers and is expressed as a percentage. Cotton with a low length uniformity may be difficult to process.

Earliness: Earliness is reported as the percentage of the total yield harvested at the first picking where more than one harvest was made.

Fusarium Wilt: Reaction of varieties to *Fusarium oxysporum* f. *vasinfectum* (Fusarium wilt) was evaluated at the Plant Breeding Unit, Tallassee. Breeder lines and selected released varieties were grown in a field with a high natural incidence of the fusarium wilt disease. In 2003, incidence of Fusarium wilt was moderate. The incidence ratings can be found in the 2003 National Fusarium Wilt Cotton Report, Departmental Series No. 255.

STATISTICAL ANALYSIS

Appropriate analyses of the yield data were made. For each location, the variability in the test was measured and expressed as a percentage of the test mean, i.e., the coefficient of variation (C.V.). An indication of the magnitude of difference between variety averages necessary to be considered a real difference is given for each location. It is designated as the Least Significance Difference (L.S.D._{.10}). Appropriate care should be taken when using multi-location or multi-year averages. The genotype x environment interaction is often a significant source of variation, indicating that the varietal rankings are not consistent from one location to another or from one year to the next. Using multi-environment means in these instances can be grossly misleading.

ACKNOWLEDGMENTS

Appreciation is also expressed to the following supervisory personnel of the outlying units whose quality work makes this a reliable source of information for farmers in their areas:

Chet Norris and Ellis Burgess, Tennessee Valley Research and Extension Center; Don Moore, Prattville Research Field; Bobby Durbin, E.V. Smith Research Center; Randy Akridge, Brewton Research Field & Huxford; Larry Wells and Brian Gamble, Wiregrass Research and Extension Center; Ronnie McDaniel and Malcomb Pegues, Gulf Coast Research and Extension Center.

EFFECT OF TELONE II ON YIELD AND QUALITY OF COTTON VARIETIES AT HUXFORD, AL 2003.

Thirty-two commercially available cotton varieties were examined with and without a nematicide in a field naturally infested with the reniform nematode in Huxford, AL. The test was planted April 30, 2003. Plots consisted of 1 row, 25 ft long with a 38 in. row spacing and replicated six times. Because of the potential for lateral movement of Telone II in the soil, treated and untreated plots were arranged as blocks within the field. Telone II was injected at 3 gal/A into plots 8 to 12 inches deep with a ripper / bedder. The plots were harvested on October 25, 2003. Reniform nematode counts, expressed as numbers per 150 cc of soil, were evaluated on three replicates within each block.

Because of the arrangements of plots mentioned above, this experiment was analyzed like an experiment replicated across environments. Thus there is no valid test for the main effect of treatment but treatment x variety interaction means are not affected. Because of the spatial structure of reniform nematode distribution in the soil we employed nearest neighbor analysis based on all four neighboring plots to account for some of the residual variability and obtain more precise estimate of differences.

All varieties tested were susceptible to the reniform nematode. Average yields for varieties evaluated with Telone II ranged from 601 (Deltapine DP 444BG/RR) to 1299 lbs/acre (Deltapine DP 555BG/RR). Yields for untreated check plots ranged from 336 (Deltapine DP 436RR) to 1072lbs/acre (Deltapine DP 555BG/RR). On the average, Telone II treated plots yielded 325 lbs/acre more lint than the check plots. Of particular interest are varieties that did not suffer yield reductions in the untreated check area compared to the Telone II treated experiment. These varieties, marked with a “‡” in the space between treated and untreated variety means in Table 25, warrant further investigations, particularly in cases where this phenomenon is associated with higher reniform counts in untreated plots.

† Variety means are sorted in descending order for lint yield from Telone II treated plots.

‡ Difference for lint yield between Telone II treatment and untreated check is not significant at $P = 0.10$.
